100%

1. Fill in the blanks of this code to print out the numbers 1 through 7.

```
1/1 point
                                                                                                     Run
         while number <= 7:
             print(number, end=" ")
number += 1
✓ Correct
      Nice job! You're really getting the hang of what goes into
      the while loops!
```

The show\_letters function should print out each letter of a word on a separate line. Fill in the blanks to make that

```
def show_letters(word):
   for w in word:
   print(w)
                                                                             Run
show_letters("Hello")
# Should print one line per letter
```

```
✓ Correct
     Great job! You're working the "for" loops the way they're
     supposed to be done!
```

Complete the function digits(n) that returns how many digits the number has. For example: 25 has 2 digits and 144 has 3 digits. Tip: you can figure out the digits of a number by dividing it by 10 once per digit until there are no digits left.

```
def digits(n):
                    count = 0
if n == 0:
return 1
while (n!=0):
                         count += 1
n //=10
                    return count
            print(digits(25)) # Should print 2
print(digits(144)) # Should print 3
print(digits(1000)) # Should print 4
    10
                                                                                                                                                     Run
                                           # Should print 1
              print(digits(0))
✓ Correct
```

4. This function prints out a multiplication table (where each number is the result of multiplying the first number of its row by the number at the top of its column). Fill in the blanks so that calling multiplication\_table(1, 3) will print out:

Woohoo! You've cracked the code of writing code!

246

369

```
def multiplication table(start, stop):
     for x in range(start, start+stop):
   for y in range(start, stop+start):
        print(str(x*y), end=" ")
           print()
                                                                                                                 Run
multiplication_table(1, 3)
# Should print the multiplication table shown above
```

```
Awesome! You've stepped up to the challenge of one of the
more complex coding practices, nested loops!
```

5. The counter function counts down from start to stop when start is bigger than stop, and counts up from start to stop

1/1 point otherwise. Fill in the blanks to make this work correctly.

```
def counter(start, stop):
     x = start
if x>stop:
          return_string = "Counting down: "
while x >= stop:
```

```
return_string += ","
                                                                     x-=1
                       9
10
                       11
                                                          return_string = "Counting up: "
                                                          while x <= stop:
return_string += str(x)
                       12
13
                                                                   if x<stop:
    return_string += ","
x+=1</pre>
                       14
15
16
                                               return return_string
                       18
                                    print(counter(1, 10)) # Should be "Counting up: 1,2,3,4,5,6,7,8,9,10"
print(counter(2, 1)) # Should be "Counting down: 2,1"
print(counter(5, 5)) # Should be "Counting up: 5"
                        19
20
                                                                                                                                                                                                                                                   Run
                       21
                ✓ Correct
                              You nailed it! You've figured out all of the situations that
                              need to be considered!
        The even_numbers function returns a space-separated string of all positive numbers that are divisible by 2, up to and 1/1 point
         including the maximum that's passed into the function. For example, even_numbers (6) returns "2 4 6". Fill in the blank and the function of t
                                    def even_numbers(maximum):
                                               return_string = ""
for x in range(2,maximum+1):
    if x%2==0:
                                                                  return_string += str(x) + " "
                                               return return_string.strip()
                                   print(even_numbers(6)) # Should be 2 4 6
print(even_numbers(10)) # Should be 2 4 6 8 10
print(even_numbers(1)) # No numbers displayed
print(even_numbers(3)) # Should be 2
print(even_numbers(0)) # No numbers displayed
                                                                                                                                                                                                                                                   Run
                       11
                       12
                ✓ Correct
                              Woohoo! You remembered all of the elements of the range of
                              the for-loop, well done!
7. The following code raises an error when executed. What's the reason for the error?
                                                                                                                                                                                                                                                                           1/1 point
                 4 return year
        O Incrementing by 10 instead of 1

    Failure to initialize variables

    Nothing is happening inside the while loop

    Wrong comparison operator

                 ✓ Correct
                          Well done! The variable year needs to be initialized prior to being used in the while loop.
8. What is the value of x at the end of the following code?
                                                                                                                                                                                                                                                                           1/1 point
                                for x in range(1, 10, 3):
                                         print(x)
                 ✓ Correct
                            You got it! The upper limit of a range isn't included, which means that the loop stops before reaching it. The
                            increment is 3, so the loop stops when \boldsymbol{x} reaches 7.
9. What is the value of y at the end of the following code?
                                                                                                                                                                                                                                                                           1/1 point
                                for x in range(10):
    for y in range(x):
        print(y)
                           Great job! The upper limit of a range isn't included, which means that the outer loop goes up to 9, so the
                            highest upper limit for the inner loop is 9, which is also not included.
```

10. How does this function need to be called to print yes, no, and maybe as possible options to vote for?

def votes(params):
for vote in params:

1/1 point
